

Turkey Treasury / ALM & Liquidity Risk Dashboard

A Real-Data Market and Banking-Sector Monitoring Case with Garanti BBVA ALM Proxy Extension

Treasury / ALM & Liquidity Risk Portfolio Case

Enes Sarı

Data through: 15 May 2026 | Case study date: 18 May 2026

Metric	Latest reading	Interpretation
Policy rate	37.0%	Monetary policy anchor
TLREF	40.0%	Overnight TL funding proxy
TLREF-policy spread	3.0 pp	Short-term funding pressure signal
USD/TRY	45.50	FX pressure monitor
Gram gold	TRY 6,651	FX/gold liquidity watch
CPI YoY	32.4%	Inflation context
Real policy rate proxy	4.6 pp	Policy rate less CPI YoY
10Y-2Y slope	-6.7 pp	Curve shape / rate-risk signal
Loan/deposit ratio	88.1%	Sector funding balance
FX deposit share	40.5%	Dollarization / deposit mix
Total reserves	USD 171,529mn	FX-gold buffer proxy
Liquidity stress score	57.0 / 100 (Elevated)	Composite dashboard signal

Table 1. Executive treasury dashboard snapshot.

Scope note: This memo is a portfolio case study. It uses public market, banking-sector, and Garanti BBVA financial statement data to construct treasury-oriented monitoring indicators and proxy ALM metrics.

1. Executive Summary

This case study builds a Turkey-focused treasury and ALM monitoring dashboard using publicly available market, macro-financial, banking-sector, and selected bank financial statement data. The dashboard tracks TL funding conditions, FX and gold liquidity pressure, inflation-adjusted rates, yield-curve movements, deposit and loan dynamics, reserves, and a composite liquidity stress score.

The core finding is that the latest dashboard reading points to an elevated but not extreme treasury stress environment: TLREF remains above the policy rate, the yield curve is inverted, FX and gold prices remain structurally higher than the 2021 base, and the banking sector loan/deposit ratio is below 100% but funding conditions remain rate-sensitive.

The Garanti BBVA extension is not presented as an internal ALM model. Instead, it uses unconsolidated financial statement line items to construct public-data-based proxies for asset/funding mix, liquidity buffer, FC balance-sheet gap, funding-cost sensitivity, and repricing-gap sensitivity.

The practical objective is to show how a treasury, ALM, or liquidity risk team could translate observable market and sector conditions into a concise management dashboard and risk memo.

2. Data and Methodology

The main dashboard is built at weekly frequency. Daily market variables are mapped to weekly observations, monthly inflation is forward-filled, and bank/sector variables are aligned to the same weekly frame where available. This allows market, macro, and balance-sheet indicators to be viewed together without claiming daily precision for slower-moving banking data.

Data block	Primary variables	Use in memo
Market funding	Policy rate, TLREF, deposit rate proxy, loan rate proxy	TL funding and margin-pressure monitoring
FX and gold	USD/TRY, EUR/TRY, gram gold, rolling volatility	FX-gold liquidity watch
Inflation and curve	CPI YoY, 2Y/5Y/10Y yields, 10Y-2Y spread	Real-rate and interest-rate risk context

Data block	Primary variables	Use in memo
Banking sector	Loans, deposits, FX deposits, KKM, securities, FX position, reserves	Liquidity, dollarization, collateral, and reserve-buffer indicators
Bank-specific extension	Garanti BBVA unconsolidated financial statements, 1Q25-1Q26	Public-data-calibrated ALM proxy analysis

3. TL Funding Conditions

The first treasury question is whether short-term market funding is aligned with the policy anchor. TLREF above the policy rate signals tighter overnight funding conditions and can pressure banks and corporates that rely on short-dated TL liquidity.

Figure 1. TL funding conditions: policy rate, TLREF, and spread.

As of 15 May 2026, TLREF stood at 39.99%, compared with a policy rate of 37.00%, implying a 2.99 percentage-point spread. For treasury monitoring, this spread is more informative than the policy rate alone because it captures the actual short-term funding environment.

4. FX and Gold Liquidity Watch

FX and gold indicators matter for Turkish treasury teams because they affect collateral values, customer dollarization behavior, FC liquidity planning, precious-metal liquidity, and hedge requirements. The indexed chart is designed to show direction and relative pressure rather than forecast exchange rates.

Figure 2. FX and gold liquidity watch: indexed USD/TRY, EUR/TRY, and gram gold.

5. Inflation, Real Rates, and Yield Curve

Nominal funding costs should be interpreted in light of inflation. A positive real policy-rate proxy supports the attractiveness of TL assets and deposit liberalization, while a negative or declining proxy can weaken the TL funding base.

Figure 3. Inflation and real rate conditions.

The yield-curve panel adds the market-rate dimension to the policy-rate story. Inverted curves and high short-end yields are relevant for securities valuation, duration management, reinvestment decisions, and the funding cost of longer-tenor liabilities.

Figure 4. Yield curve and interest-rate risk: 2Y/5Y/10Y yields and 10Y-2Y slope.

6. Banking-Sector Liquidity Conditions

The banking-sector block connects market rates to balance-sheet behavior. The loan/deposit ratio is a simple but useful proxy for funding balance: a rising ratio may indicate stronger credit extension relative to deposit funding, while a lower ratio suggests greater deposit-funded balance-sheet capacity.

Figure 5. Banking-sector liquidity: loans, deposits, and loan/deposit ratio.

Deposit composition is equally important. FX deposit share captures dollarization and FC funding behavior, while KKM share tracks the legacy stock of FX-protected TL deposits and the transition toward standard TL deposits.

Figure 6. Deposit structure: FX deposit share and KKM share.

7. Composite Treasury Liquidity Stress Score

To turn the dashboard into a management signal, the project builds a composite liquidity stress score. The score combines funding pressure, FX/gold volatility, curve inversion pressure, banking liquidity dynamics, FX deposit behavior, and reserve-buffer changes. The score is normalized to a 0-100 scale and labelled as Low, Moderate, Elevated, or High.

Figure 7. Composite treasury liquidity stress score.

The latest score is 57.0/100, classified as Elevated. The score should not be interpreted as a regulatory metric; it is a dashboard signal designed to prioritize monitoring and scenario discussion.

8. Garanti BBVA Bank-Specific ALM Proxy Extension

The preceding sections use public market and banking-sector data. Institution-level ALM metrics such as contractual cash-flow ladders, regulatory LCR, internal FTP curves, and true NII sensitivity require confidential internal bank data. To avoid overstating precision, this section uses Garanti BBVA unconsolidated financial statements to build a public-data-calibrated ALM proxy extension.

Figure 8. Garanti BBVA ALM proxy snapshot based on public financial statement inputs.

Metric	Latest bank proxy reading	Interpretation
Total assets	TL 4,016.8bn	Balance-sheet scale used for proxy extension
Loans / assets	60.7%	Earning asset concentration
Liquid assets / assets	31.5%	Cash and securities liquidity buffer proxy
Loan / deposit ratio	89.9%	Bank-level funding balance proxy
Liquid assets / deposits	46.6%	Simple liquidity buffer relative to deposits
FC deposits / deposits	37.1%	Bank-specific dollarization/funding mix proxy
Balance-sheet FC gap / equity	-33.0%	Balance-sheet currency mismatch proxy

9. Maturity Ladder and Scenario Sensitivity

The maturity ladder is stylized, but it is calibrated from the latest bank financial statement line items. It is not a behavioral internal ALM cash-flow ladder. Its purpose is to demonstrate the mechanics of translating liquid assets, securities, loans, deposits, and wholesale funding into a maturity-bucket view.

Figure 9. Garanti BBVA maturity ladder proxy and weighted funding cost scenario.

Scenario	Assumption	Expected treasury impact	Management monitoring point
Base case	Current market rates and current balance-sheet structure	Normal monitoring; elevated rate sensitivity remains	Track TLREF-policy spread, deposit costs, and reserve buffer
FX depreciation stress	USD/TRY +10%; FX/gold	Potential dollarization pressure and	Monitor FC deposits, FC position, reserve

Scenario	Assumption	Expected treasury impact	Management monitoring point
	volatility rises	FC liquidity focus	buffer, and hedge needs
Rate volatility stress	TLREF +300 bps; short-end yields stay elevated	Higher funding cost and potential NII pressure if liabilities reprice faster	Repricing gap, deposit beta, securities duration, wholesale rollover
Liquidity tightening	Deposit outflows increase; wholesale rollover becomes costlier	Liquidity buffer requirement rises; coverage proxy weakens	Short-term cash-flow ladder, collateral availability, repo capacity
Rate-cut scenario	Policy and market rates decline by 200 bps	Funding cost relief but possible compression depending on asset repricing	Deposit repricing speed, asset yield reset, customer behavior
Scenario	Rate shock	Estimated annual NII impact	Interpretation
Rate cut -200 bps	-2.0 pp	TL 15.0bn	Positive in this proxy because liabilities are assumed to reprice faster
Rate shock +100 bps	+1.0 pp	TL -7.5bn	Negative repricing-gap impact
Liquidity tightening +300 bps	+3.0 pp	TL -22.6bn	Amplifies funding and margin pressure

10. Conclusion and Application Relevance

The case demonstrates a practical treasury workflow: collect public data, standardize frequencies, build core funding and liquidity metrics, translate market signals into risk labels, and connect sector-level indicators to a selected-bank ALM proxy. The main value of the project is not a single forecast or target value, but a structured monitoring system that can be adapted to bank treasury, corporate treasury, ALM, liquidity risk, money market operations, or treasury technology roles.

The strongest application signal is the combination of real data, clean dashboard design, transparent proxy construction, and management-style interpretation. The analysis is deliberately conservative about what cannot be observed from public data: it does not claim to reproduce a bank's internal LCR, FTP, behavioral cash-flow ladder, or true NII model.

Appendix A - Supporting Charts and Method Notes

Data block	Source / file family	Frequency treatment	Main use
Policy rate	TCMB 1-week repo rate	Decision dates carried forward to weekly	Policy anchor
TLREF	BIST TLREF historical data	Daily to weekly observation	Overnight TL funding proxy
FX and gold	USD/TRY, EUR/TRY, GAU/TRY market data	Daily to weekly observation	FX/gold liquidity watch
Inflation	TCMB/TURKSTAT CPI YoY	Monthly forward-filled to weekly	Real policy-rate proxy
Yields	Turkey 2Y/5Y/10Y public yield data	Daily to weekly observation	Yield curve and duration risk
Banking sector	Loans, deposits, securities, FX position, reserves	Weekly alignment	Sector liquidity and stress score
Selected bank	Garanti BBVA unconsolidated financials, 1Q25-1Q26	Quarterly bank-specific extension	ALM proxy inputs

Appendix Table A1. Data sources, frequency treatment, and dashboard use.

Appendix Figure A1. FX and gold rolling volatility.

Appendix Figure A2. Loan growth vs deposit growth.

Appendix Figure A3. Deposit composition: demand/term and customer-type shares.

Appendix Figure A4. FX general position and capital-relative FX risk.

Proxy item	Construction	Caveat
Liquidity coverage proxy	Post-haircut cash + securities divided by stressed outflows	Not a regulatory LCR calculation; no HQLA classification or 30-day regulatory outflow engine
Maturity ladder proxy	Latest bank balance-sheet line items distributed into maturity buckets with explicit assumptions	Not an internal behavioral cash-flow ladder; no deposit stickiness or prepayment model
Market-implied funding cost	Funding mix from bank financials combined with public market rate proxies	Not internal FTP; does not reflect product-level transfer pricing or liquidity premiums
NII / repricing sensitivity	Rate-sensitive assets minus rate-sensitive liabilities multiplied by rate shock	Not a bank internal NII simulation; simplified repricing assumptions
FX gap proxy	Balance-sheet FC assets less FC non-equity liabilities, scaled by equity	Does not fully model off-balance-sheet hedge accounting or internal risk limits

Appendix Table A2. ALM proxy methodology and caveats.

Appendix B - Source Notes

Main sources used: TCMB/EVDS, BIST TLREF, BDDK/BRSA banking-sector data, public FX/gold/yield data, Garanti BBVA annual reports, Corporate Presentation May 2026, and quarterly unconsolidated financial statements through 31 March 2026.

All public-data proxy metrics are analytical demonstrations, not regulatory calculations, sell-side investment advice, or internal bank management reports.
